(54) Title: BIT-INTERLEAVED RATE 16/17 MODULATION CODE WITH THREE-WAY BYTE-INTERLEAVED ECC

(57) Abstract

A modulation method generates a rate 16/17 ($d = 0$, $G = 7/11 = 11$) modulation code for transferring user digital data bytes having a three-way ECC interleave through a data transfer channel in accordance with the steps of: shuffling (112, 114) the user data bytes in order to rearrange an order of the bytes in a predetermined manner and putting out $A_i B_i$ byte pairs, encoding (116) eight bits of the A_i bytes of the $A_i B_i$ byte pairs in accordance with a predetermined rate 8/9 modulation code to produce nine code bits a_0 - a_8 , and interleaving (130) the nine code bits a_0 - a_8 of each A_i byte with eight unencoded bits of each B_i byte in accordance with a predetermined bitwise interleave pattern to generate the rate 16/17 modulation code. A preferred code and circuitry for the modulation method are also described.

BIT-INTERLEAVED RATE 16/17 MODULATION CODE WITH THREE-WAY BYTE-INTERLEAVED ECC

Field of the Invention

5 The present invention relates to channel modulation codes and methods. More particularly, the present invention relates to a rate 16/17 channel code compatible with lowered-overhead, three-way interleaved ECC.

Background of the Invention

10 Modulation codes have been employed within magnetic recording channels in order to achieve a more even distribution of magnetic flux transitions within a data track in view of data patterns of particular user information being encoded and recorded. In particular, run length limited (RLL) modulation codes have been employed within partial response
15 signaling, maximum likelihood detection (PRML) data recording and playback channels, decision feedback equalization (DFE) channels, and fixed delay tree search (FDTS) channels.

20 Partial response channels of interest for magnetic data storage devices include a (1-D) dicode channel, a PR4 (1-D²) channel and an EPR4 (1+D-D²-D³) channel. In these systems Viterbi detectors are frequently employed to achieve maximum likelihood detection of user data being played back from the recording medium. A modulation code for a PRML data recording and
25 playback channel is selected to balance code efficiency against timing/gain loop reliability and Viterbi detector path memory.

30 At the same time, error correction code (ECC) techniques are employed in order to detect, locate and correct error bursts within a data stream received as play back from the magnetic recording channel. In order to
35 perform ECC, an encode process appends ECC remainder bytes to the unencoded data stream prior to encoding, precoding and recording. During playback, following postcoding, and modulation decoding the remainder bytes are checked in each ECC interleave for errors. If one or several burst errors are determined to be present, the remainder bytes are employed by ECC
processes to locate and correct the error burst(s). The number of ECC remainder bytes is a function of the number of interleaves, the sector or block length, and of the robustness of the ECC process in locating and correcting multiple burst errors (errors spanning plural data interleaves). The interested

reader is referred to Peterson and Weldon, Error-Correcting Codes, Second Edition, The MIT Press, Cambridge, Massachusetts, © 1972, and also to commonly assigned U.S. Patent No. 5,241,546 to Peterson et al., entitled: "On-The-Fly Error Correction with Embedded Digital Controller", the disclosure thereof being incorporated herein by reference. This patent explains the division of a user data block of e.g. 512 bytes into three ECC interleaves, wherein interleaves 1 and 2 each contains e.g. 171 data bytes, and interleave 3 contains e.g. 170 data bytes. ECC interleave 1 includes e.g. bytes [1], [4], [7], [10]. . .etc.; interleave 2 includes e.g. bytes [2], [5], [8], [11]. . .etc.; and, interleave 3 includes e.g. bytes [3], [6], [9], [12]. . .etc. In effect, each interleave becomes its own error correction channel having its own remainder bytes. By employing interleaves within the ECC process, the ECC symbol length is shortened (e.g. 512 bytes to 171 or 170 bytes), which in turn reduces the complexity of the error correction process, simplifies the implementing hardware/firmware, speeds up execution of corrections, and accommodates single burst error lengths of up to three bytes.

For example, Fig. 1 illustrates a conventional PRML magnetic recording channel including ECC. A stream 12 of incoming user data bytes is subjected to ECC encoding within an ECC encoder 14 which appends remainder bytes for each interleave at the end of each data block. Cross-check bytes may also be appended by the ECC encoder 14 for purposes explained in commonly assigned U.S. Patent No. 5,422,895 issued on June 6, 1995, entitled: "Cross-Checking for On-The-Fly Reed Solomon Error Correction Code", the disclosure thereof being incorporated herein by reference. Each data block is then encoded in accordance with desired modulation code, such as a rate 8/9 code, by an encoder 16. A precoder 18 then precodes the data in order to conform it to a predetermined spectrum, such as partial response, class IV (PR4) for example. The encoded and precoded blocks are then recorded by digital saturation recording onto a magnetic storage medium 20.

During playback, analog data is low pass filtered and sampled by an analog to digital conversion process 22 and equalized to the PR4 spectrum by analog and/or digital filtering 24. Because PR4 is present, the data is essentially interleaved, and a selector 26 directs equalized samples alternately to two Viterbi detectors 28A and 28B. The Viterbi detectors perform maximum likelihood detection of the interleaved sample sequences, and a downstream selector 30 reassembles the detected binary values into code

words which are then post-coded by a post-coder 32, and decoded by a decoder 34, and then checked in an ECC decoder 36 to see if any error bursts are present. If not, the decoded data bytes 38 are delivered to a requesting process. If one or more error bursts are detected, the ECC process 36 then
5 begins a correction process not directly pertinent to the present invention. One example of a prior art magnetic recording and playback channel is provided in commonly assigned U.S. Patent No. 5,341,249 entitled: "Disk Drive Using PRML Sampling Data Detection with Digital Adaptive Equalization", the disclosure thereof being incorporated herein by reference.

10 The relevant technical literature provides examples of rate 8/9 ($d=0$, $G=4/I=4$) modulation codes, see e.g. U.S. Patent No. 4,707,681 and commonly assigned U.S. Patent No. 5,260,703. These patents describe the utility and advantages of rate 8/9 modulation codes within the field of magnetic
15 recording. As the code rate approaches unity, the code is deemed to be more efficient, in that relatively fewer code characters are required to encode user data values. Thus, a rate 8/9 code is more efficient than a rate 2/3 code. Similarly, a rate 16/17 code is more efficient than a rate 8/9 code. For example, a rate 16/17 ($\approx .941$) modulation code achieves an approximately six
20 percent (6%) increase in recording density over a standard rate 8/9 modulation code.

While rate 16/17 modulation codes are more efficient than rate 8/9 modulation codes, some rate 16/17 modulation codes have certain drawbacks.
25 For example, the reader is referred to commonly assigned, copending U.S. Patent Application Serial No. 08/497,182, filed on June 30, 1995, entitled: "A Rate 16/17 ($d=0, G=6/I=7$) Modulation Code" for a description of an improved rate 16/17 modulation code (this prior application is incorporated herein by reference). While this prior approach works very successfully, it requires a
30 four-way ECC interleave, as compared to a three-way ECC interleave for a rate 8/9 ($0,4/4$) code. The four-way ECC interleave requirement somewhat negates the benefits of the improved rate 16/17 modulation code efficiency, because of the need for extra ECC remainder bytes which increases channel overhead by about one percent (1%). Also, four-way ECC interleave
35 increases the ECC circuitry and expense of implementation.

Since the Viterbi detectors 28A and 28B each include a path memory of predetermined length, every error event can corrupt more than one bit. With

a standard PR4 precoding and a PR4 Viterbi detector 28A or 28B, one error event will corrupt two bits, separated by some span of uncorrupted bits. Thus, when a bit becomes corrupted e.g. by misdetection within the Viterbi detector 28A or 28B, a whole codeword becomes corrupted, and if a bit error
5 happened to straddle a codeword boundary, then two codewords would become corrupted.

If a rate 16/17 block code is employed, as exemplified in Fig. 2, a single bit error could corrupt four bytes. So, if there were four bytes of a code
10 word that were corrupted, and the four byte codeword spanned two ECC interleaves, the ECC correction process 36 would consider the single error event and its consequence in the Viterbi detector to constitute a double burst error, which is much more difficult to locate and correct than a single burst error. Thus, in selecting a suitable rate 16/17 modulation code, it is not
15 reasonable to accept a consequence that a single bit corruption would lead to a corruption of a number of bytes spanning error correction interleaves.

Fig. 3 illustrates one known rate 16/17 modulation code which interleaves rate 8/9 (0,4/4) code bytes with unencoded bytes. One practical
20 drawback of this code is that its characteristics are (0,12/8) meaning that while each interleave is 8 bits long, the maximum zero run length is 12 bits (clock cells or positions), a run length which is unduly long and may lead to loss of timing synchronization and phase lock by the sampling loop which controls timing for taking the digital samples of the signal recovered from the
25 magnetic medium. For example, in Fig. 3, if an unencoded data byte happened to be all zeros, and the last two bits of a leading code word were also zeros, and the first two bits of a trailing code word were zeros (both conditions being within the coding constraints of the rate 8/9 (0,4/4) modulation code), a maximum uninterrupted string of zeros would equal 12.

30 Thus, a hitherto unsolved need has remained for a rate 16/17 modulation code having reasonable zero run-length properties and which enables use of three-way interleaved ECC.

35 Summary of the Invention with Objects

A general object of the present invention is to provide a new rate 16/17 ($d=0, G=7/I=11$) modulation code overcoming limitations and drawbacks of the prior art.

5 A more specific object of the present invention is to provide a rate 16/17 modulation code employing bit-wise interleaving of code words and byte reordering in order to achieve reasonable run-length properties while requiring only three-way interleaved ECC in a manner overcoming limitations and drawbacks of the prior art.

10 Another object of the present invention is to provide a rate 16/17 modulation code which limits single bit errors to consequences approaching those occurring within a conventional rate 8/9 ($0,4/4$) modulation code in response to single bit errors.

15 One more object of the present invention is to provide a rate 16/17 modulation code which includes a rate 8/9 RLL(0,3) modulation codewords without interleave constraint which are bit-interleaved with uncoded bytes.

20 In accordance with principles of the invention, a method for generating a rate 16/17 modulation code for transferring user digital data bytes having a three-way ECC interleave through a data transfer channel comprises the steps of:

25 shuffling the user data bytes in order to rearrange an order of the bytes in a predetermined manner and putting out $A_i B_i$ byte pairs,

encoding eight bits of the A_i bytes of the $A_i B_i$ byte pairs in accordance with a predetermined rate 8/9 modulation code to produce nine code bits a_0 - a_8 , and

30 interleaving the nine code bits a_0 - a_8 of each A_i byte with eight unencoded bits of each B_i byte in accordance with a predetermined bitwise interleave pattern to generate the rate 16/17 modulation code.

These and other objects, advantages, aspects and features of the present invention will be more fully understood and appreciated upon
35 consideration of the following detailed description of a preferred embodiment, presented in conjunction with the accompanying drawings.

Brief Description of the Drawings

In the Drawings:

Fig. 1 is a simplified block diagram of a conventional PRML magnetic recording and playback channel.

Fig. 2 is a diagram of a single error event which becomes propagated across multiple code words and ECC interleaves, thereby presenting a multiple burst error condition to an ECC process.

Fig. 3 is a diagram of a prior rate 16/17 (0,12/8) modulation code having less than desirable zero run length properties.

Fig. 4 is a set of graphs illustrating implementation of a rate 16/17 modulation code in accordance with principles of the present invention.

Fig. 5 is a block diagram of an encoding process for a magnetic recording channel incorporating principles of the present invention.

Fig. 6 is a block diagram of a bitwise interleave process within the encoding process of Fig. 5 incorporating principles of the present invention.

Fig. 7 is a block diagram of a decoding process for the magnetic recording channel illustrated in Fig. 5, incorporating principles of the present invention.

Detailed Description of a Preferred Embodiment

In order to understand the present invention, it should be appreciated that the Viterbi detectors 28A and 28B of Fig. 1 are actually two independent channels. Accordingly, if one of the Viterbi detectors 28 makes an error, it will occur in one channel, but not in both channels. If, for example, all of the even bits were within one channel; and, all of the odd bits were in the other channel, then an error event occurring in the even bit stream in the one channel, even at a location straddling a codeword boundary, the data would only be corrupted in the even bit stream in the one channel, and not in the other channel.

Three fundamental steps are taken in order to realize a desired rate 16/17 modulation code having reasonable zero run length properties as well as enabling use of three-way interleaved ECC. First, codewords are interleaved on a bit-by-bit ("bitwise") basis. Second, the codewords to be interleaved must have certain desired properties. Third, byte reordering is carried out.

Once bitwise encoding is envisioned, the codewords must be chosen. One likely candidate is to interleave on a bitwise basis a codeword in accordance with the rate 8/9 RLL (0,4/4) code described in commonly assigned U.S. Patent No. 5,260,703 with an unencoded codeword (e.g. byte), which produces a new rate 16/17 modulation code.

In the (0,4/4) code, the zero specifies the minimum number of zeros (timing cells or units having no transition) between successive ones (cells having transitions), the first four specifies the maximum number of consecutive ones, and the second four specifies the maximum number of cells in an interleave. If A represents a bit of a rate 8/9 (0,4/4) codeword (nine bits) and U represents a bit of an unencoded codeword (eight bits), then graph A of Fig. 4 illustrates three bitwise interleaved codewords in accordance with the new rate 16/17 modulation code.

It will be appreciated by those skilled in the art that only the global runlength constraint of the original (0,4/4) code is significant in the new code illustrated in graph A of Fig. 4. Accordingly, an RLL (0,3) code may be employed with certain advantages. The (0,3) code benefits from a tighter global runlength constraint because the interleave constraint has been eliminated. Also, the (0,3) encoder/decoder is structurally simpler than the (0,4/4) encoder/decoder described in U.S. Patent No. 5,260,703 referenced above, and this increased simplicity will help to offset a modest increase in complexity caused by the new interleave/deinterleave circuit.

One can assume that the worst-case runs of zeros occur when the unencoded words are always zero, i.e. $U=0$. Since at most only three consecutive bits within the encoded codeword (A bits) can be zero because of the maximum zero run length of three, the maximum global run length of zeros for the new code is seven. This occurs when four unencoded zeros are interleaved with three encoded zeros, as shown in graph B of Fig. 4. The maximum run of zeros in each interleave of the code is 11, which can occur

when 8 unencoded zeros are concatenated with three encoded zeros within the same interleave, also as graphed in graph B of Fig. 4. Thus, the new rate 16/17 modulation code has the desirable properties of ($d=0$, $G=7/I=11$).

5 Bitwise interleaving is effective because errors normally do not occur simultaneously in both odd and even bit interleaves due to the fact that partial
10 response, class IV (PR4) uses the two interleaved Viterbi detectors 28A and 28B, shown in Fig. 1. Thus, the odd and even bitstreams are relatively independent. It would be very unlikely to have an error event which both straddled a codeword boundary and occurred simultaneously in both interleaves. In the unlikely event of a straddling event in both interleaves, four bytes would be corrupted.

15 In order for the three-way interleaved ECC to work properly with the new rate 16/17 RLL(0,7/11) modulation code, the following steps are carried out in order to alternate between encoding (rate 8/9) the even and odd bytes and then bitwise interleaving bits into resultant codewords:

1. Unencoded incoming user bytes $U_0 U_1 U_2 U_3 U_4 U_5 U_6 U_7$, etc. are
20 shuffled to:

$U_0 \ U_1 \ U_3 \ U_2 \ U_4 \ U_5 \ U_7 \ U_6, \text{ etc.}$

(This shuffle pattern applies to a three-way ECC interleave; a four-way ECC interleave will have a different shuffle pattern.)

25 2. The shuffled bytes are then selectively encoded as follows:

$A_0 B_0 | A_1 B_1 || A_2 B_2 | A_3 B_3 || \dots$, where A_i represents rate 8/9 RLL (0,3) encoded bytes and wherein B_i represents unencoded bytes.

30 3. The selectively encoded AiBi codewords are then bitwise interleaved into the following sequence:

abababababababalababababababababalabababababababala . . . , etc.

3 5 It is to be understood that U_0, U_1 , etc., is the sequence of user bytes from the controller 102; A_0, A_1 , etc., are rate 8/9 RLL(0,3) encoded bytes from the 8/9 encoder 116 and B_1, B_2 , etc., are unencoded user bytes, and pairs of the A_i, B_i bytes become bitwise interleaved within the bitwise interleave process 130, described below in connection with Fig. 5.

Typical byte error sequences resulting from a PR4 detection with a $PW50/T < 2.2$ (approx.) are B_0A_1 , A_0B_1 , $A_0B_1A_2$, B_1A_2 , and $A_1B_2A_3$. An error sequence in codewords A_0B_0 , A_0B_1 , A_1B_1 , and A_2B_2 are shown in graph C of Fig. 4. Thus, in graph C, if an error occurs at a last bit position in the A_0B_0 codeword, and the B_1 byte contains all zeros, it is possible that the error would propagate over the A_1B_1 codeword to corrupt the first bit of the A_2B_2 codeword, at the locations shown by the two arrows in Fig. 4c. By inspecting the resulting decoded U_i sequence in each case, it can be seen that these error sequences never corrupt more than one byte per ECC interleave. One interesting error case is $A_iB_{i+1}A_{i+2}$, where ECC interleaves 0 and 2 are corrupted with errors A_i and B_{i+1} , and interleave 1 is corrupted with error A_{i+2} . However, in the less likely case of simultaneously corrupting both (Viterbi channel) interleaves, at worst case four bytes will become corrupted. In most cases only three bytes will be impacted.

Figs. 5 and 7 respectively illustrate pertinent portions of an encode path and a decode path within a PRML magnetic recording channel. While a disk channel is illustrated, a tape channel is readily within the contemplation of the present invention. User data bytes are received into a data controller 102 from a source, such as a digital computer (not shown) to which the magnetic recording channel is operatively attached. During an encoding operation in which one or more blocks of user data bytes are to be recorded to a magnetic storage medium, such as a rotating magnetic disk 132, the controller 102 passes the user bytes through an ECC encoder which appends e.g. ECC remainder bytes for each one of three ECC interleaves, and puts out each data block and its appended ECC remainder bytes as a stream of e.g. 4-bit nibbles which are accumulated in a serial to parallel converter 104 into e.g. 16 bit words. The accumulated words are clocked out of the converter 104 by an interface word clock asserted via a path 106. A data randomizer 108 then randomizes the user bytes in a one-to-one mapping in known fashion to remove recurrent data patterns and to present a more evenly randomized sequence to a subsequent encoding process. The data randomizer 108 is enabled by a `WRITE_ENABLE` control asserted over a path 110.

The 16 bit word output from the data randomizer 108 is divided into two byte-wide paths, each of which is supplied as inputs to two multiplexers 112 and 114 which together shuffle the bytes from $U_0 U_1 U_2 U_3, \dots$ etc., to $U_0 U_1 U_3 U_2, \dots$ etc., as explained above. Shuffled bytes selected by the

5 multiplexer 112 are then sent through an 8/9 RLL (0,3) encoder 116 which encodes each 8-bit byte into nine bits which are put out as nine high order coded bits [8:17] onto a path 118. Shuffled bytes selected by multiplexer 114 are put out as eight low order unencoded bits onto the path 118. A byte
10 shuffle control on a path 120 is provided for controlling the multiplexers 112 and 114. The byte shuffle control is generated by a logic array comprising two D flip-flops 122 and 124, and a feedback inverter 126 connected as shown in Fig. 5. The registers 122 and 124 are clocked by a word clock signal on a path 128, and are cleared by the write_enable signal on the path 110.

15 The 17 bit shuffled word is then applied to a bitwise interleave circuit 130, shown functionally in Fig. 6. The bitwise interleave circuit 130 interleaves the bits of the incoming 17 bit word into bitwise interleaved codewords shown in graph A of Fig. 4. A parallel to serial converter 131
20 then converts each bitwise interleaved codeword into a serial bit stream which is supplied via suitable write precompensation/driver/head select circuitry to a recording element 134 which writes the bit stream onto the magnetic storage medium, such as disk 132 via conventional current saturation recording technology.

25 Turning to Fig. 7, during playback, the magnetic transducer element 134 (which may include a magnetoresistive read element) reads a flux pattern representing the recorded bit stream. A preamplifier 136 preamplifies the analog signal. A sampler, such as an analog to digital converter 138 then
30 synchronously samples the analog signal to produce a sequence of discrete samples. Equalization, e.g. to the PR4 spectrum, occurs either upstream of the sampler, or downstream of the sampler (or at both locations as taught in commonly assigned U.S. Patent No. 5,341,249 entitled: "Disk Drive Using PRML Sampling Data Detection with Digital Adaptive Equalization", the disclosure thereof being incorporated herein by reference). A digital
35 equalizer 140, such as a FIR filter, is shown in Fig. 7. A Viterbi detector 142 includes two internal Viterbi detectors, such as the detectors 28A and 28B as shown in Fig. 1.

Following Viterbi detection and merging of the two Viterbi interleaves, a serial to parallel converter 144 converts the resultant data stream into 17 bit codewords. A bitwise de-interleave process 146 then follows as an inverse of the process of the bitwise interleave process 130. The resultant data words

comprise $A_i B_i$ bytes in which the rate 8/9 encoded A_i bytes are then passed through an 8/9 decoder 150 while the unencoded B_i bytes are not decoded. The resultant 16 bit U_i and U_{i+1} bytes are then deshuffled in a byte deshuffler 152 which operates as an inverse of the byte shuffler 111, and they are then

5 derandomized in a data derandomizer 154 which operates as an inverse of the data randomizer 108 to provide unscrambled user bytes. The user bytes are then converted into e.g. 4-bit nibbles within a parallel to serial converter 150 and are fed back into the controller 102 which includes an ECC decoder for recovering and checking the ECC remainder bytes appended for each of the

10 three ECC interleaves. If no errors are discovered, the bytes are ready for delivery to the requesting process.

Here follows a description in Verilog programming language of logic equations for implementing the rate 8/9 (0,3) encoder 116 (in which a

15 resultant block code does not include the following words: 11111111, 101010101, 010101010, 001001001, 010010010, and wherein "&" =AND; "|" = OR; "^" = XOR; and, "!" = NOT logical operations):

```

Here follows a description in the Verilog programming language of logic equations for implementing the rate 8/9 (0,3) block code decoder 150:

```

    input [8:0] inword;
    output [7:0] outword;
    wire c1,n,n1,n2,n3,n4,n5;
30    assign c1 = !inword[1]&inword[2]&!inword[4]&inword[5];
    assign n = inword[0]&inword[1]&inword[4]&inword[5]&
        inword[7]&!inword[8];
    assign n1 = n & inword[2]&inword[3]&inword[6];
35    assign n2 = n & !inword[6];
    assign n3 = n & inword[2]&!inword[3];
    assign n4 = n & !inword[2]&inword[3];
    assign n5 = n & !inword[2]&!inword[3];

```

```

    assign outword[0] = ((inword[0] & (inword[8]!(!inword[1]&
        inword[2]&(inword[5]inword[6]))))&!n) ln1ln2;
    assign outword[1] = ((inword[1] & (inword[8]inword[0]|
        (!inword[5]&!(inword[4]&inword[3]&inword[6]))))
5        &!n) ln1ln5;
    assign outword[2] = ((inword[2] & (inword[8]inword[0]|
        (inword[1]&!inword[5]))&!n) ln1ln2ln4;
    assign outword[3] = (((inword[3] & (inword[8]!(inword[0]&
        (inword[4]inword[2]&(inword[5]inword[6]))))&
10        (!inword[0]&!inword[8]& (!inword[1]&inword[2]|
        inword[1]&!inword[5]&inword[3]&inword[4]))&!n) ln1;

25        &inword[1]&!inword[5])!(inword[0]&!(inword[2]&
        inword[5]))))&!n) ln1ln3.

```

Having thus described an embodiment of the invention, it will now be appreciated that the objects of the invention have been fully achieved, and it
 30 will be understood by those skilled in the art that many changes in construction and widely differing embodiments and applications of the invention will suggest themselves without departing from the spirit and scope of the invention. The disclosure and the description herein are purely illustrative and are not intended to be in any sense limiting.

35

1. A method for generating a rate 16/17 modulation code for transferring user digital data bytes having a three-way ECC interleave through a data transfer channel comprising the steps of:

5 shuffling the user data bytes in order to rearrange an order of the bytes in a predetermined manner and putting out $A_i B_i$ byte pairs,

encoding eight bits of the A_i bytes of the $A_i B_i$ byte pairs in accordance with a predetermined rate 8/9 modulation code to produce nine code bits a_0 - a_8 , and

10 interleaving the nine code bits a_0 - a_8 of each A_i byte with eight unencoded bits of each B_i byte in accordance with a predetermined bitwise interleave pattern to generate the rate 16/17 modulation code.

2. The method set forth in claim 1 comprising the further steps of: converting the generated rate 16/17 modulation code into a serial bit stream
15 and recording the serial bit stream upon a magnetic data storage medium.

3. The method set forth in claim 1 comprising the further step of randomizing the bits of the user data bytes in a known manner before the shuffling step.
20

4. The method set forth in claim 1 wherein the encoding step comprises the step of encoding the A_i bytes with a rate 8/9 RLL(0,3) modulation code without including an interleave constraint.

25 5. The method set forth in claim 2 comprising the following additional steps:

playing back the recorded serial bit stream from the magnetic data storage medium to recover recorded information,

30 equalizing the recorded information to a predetermined partial response spectrum,

synchronously sampling the recorded information to produce synchronous samples,

35 passing the synchronous samples through two interleave Viterbi detectors to provide maximum likelihood estimates of the recorded information and merging the maximum likelihood estimates into recovered codewords,

bitwise deinterleaving the recovered codewords inversely of the bitwise interleaving step to produce $A_i B_i$ recovered byte pairs,

decoding the recovered Ai bytes of each byte pair in accordance with an inverse of the rate 8/9 modulation code to provided decoded Ai bytes,

5 deshuffling the AiBi decoded byte pairs in accordance with an inverse of the step of rearranging an order of the bytes in a predetermined manner, to provide recovered bytes.

6. The method set forth in claim 5 comprising the further step of passing the recovered bytes through a three-way interleaved ECC to recover and check appended ECC remainder bytes to determine if any errors are
10 present in the recovered bytes.

7. The method set forth in claim 3 comprising the further steps of: playing back the recorded serial bit stream from the magnetic data storage medium to recover recorded information,
15 equalizing the recorded information to a predetermined partial response spectrum,

 synchronously sampling the recorded information to produce synchronous samples,

20 passing the synchronous samples through two interleave Viterbi detectors to provide maximum likelihood estimates of the recorded information and merging the maximum likelihood estimates into recovered codewords,

 bitwise deinterleaving the recovered codewords inversely of the bitwise interleaving step to produce AiBi recovered byte pairs,

25 decoding the recovered Ai bytes of each byte pair in accordance with an inverse of the rate 8/9 modulation code to provided decoded Ai bytes,

 deshuffling the AiBi decoded byte pairs in accordance with an inverse of the step of rearranging an order of the bytes in a predetermined manner, and

30 derandomizing inversely of the known randomization manner the deshuffled and decoded AiBi byte pairs , to provide recovered bytes.

8. The method set forth in claim 7 comprising the further step of passing the recovered bytes through a three-way interleaved ECC to recover and check appended ECC remainder bytes to determine if any errors are
35 present in the recovered bytes.

9. A rate 16/17 ($d=0, G=7/I=12$) modulation code for a magnetic recording channel comprising a bitwise interleave sequence: abababababababalabababababababalababababa . . . , where "a" represents a bit position within a rate 8/9 ($d=0, k=3$) run length limited nine-bit code word encoded from a data byte A_i , where "b" represents a bit position within an unencoded eight-bit data byte B_i , and where data bytes A_i and B_i have been reordered from an original incoming byte order.

10. A modulation code encoder for generating a rate 16/17 modulation
10 code for transferring user digital data bytes having a three-way ECC
interleave through a data transfer channel comprising:

a shuffler for shuffling the user data bytes in order to rearrange an order of the bytes in a predetermined manner and for putting out A_iB_i byte pairs,

15 a byte encoder for encoding eight bits of the A_i bytes of the A_iB_i byte pairs in accordance with a predetermined rate 8/9 modulation code to produce nine code bits a_0 - a_8 , and

an interleave circuit for interleaving the nine code bits a0-a8 of each Ai byte with eight unencoded bits of each Bi byte in accordance with a predetermined bitwise interleave pattern to generate the rate 16/17 modulation code.

11. The modulation code encoder set forth in claim 10 further comprising:

25 a parallel to serial converter for converting the generated rate 16/17
modulation code into a serial bit stream and a recording channel for recording
the serial bit stream upon a magnetic data storage medium.

12. The modulation encoder set forth in claim 10 further comprising a
30 data randomizer for randomizing the bits of the user data bytes before the
shuffler to randomize the data patterns of the user data bytes in a known
manner.

13. The modulation encoder set forth in claim 10 wherein the byte
35 encoder encodes the A_i bytes in accordance with a rate 8/9 RLL(0,3)
modulation code.

5 an equalizer circuit for equalizing the recorded information to a
predetermined partial response spectrum,

two interleave Viterbi detectors through which the synchronous samples
10 are passed in order to provide maximum likelihood estimates of the recorded
information and merging the maximum likelihood estimates into recovered
codewords,

a decoder for decoding the recovered A_i bytes of each byte pair in accordance with an inverse of the rate 8/9 modulation code to provided decoded A_i bytes,

15. The circuit set forth in claim 13 further comprising a three-way interleaved ECC through which the recovered bytes are passed in order to recover and check appended ECC remainder bytes to determine if any errors are present in the recovered bytes.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US96/12970

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : H03M 7/00, 9/00, 13/00; G11B 5/09, 20/14, 20/16

US CL : 371/37.1, 37.5, 38.1, 39.1; 341/59, 95, 100, 101; 360/40,46

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 371/37.1, 37.4, 37.5, 37.6, 37.7, 38.1, 39.1; 341/59, 95, 100, 101; 360/40,46

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS

search terms: interleav? and (shuffl? or rearrang? or reorder?) and modulation code# ...

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US96/12970

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 9
because they relate to subject matter not required to be searched by this Authority, namely:

Claim 9 does not fall under any of the statutory classes. More specifically, the claimed invention is neither a machine nor a process.
2. ☐ Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

☐
☐

- The additional search fees were accompanied by the applicant's protest.
No protest accompanied the payment of additional search fees.
